

The Linux & Open Source Company

Scaling Foreman Compute Provisioning with OpenTofu

A Generic, Extensible Approach to Host Provisioning

Manisha Singhal, Markus Bucher

Agenda

- 1 Foreman's current compute model
- 2 'Issues' with the current model
- 3 Introducing the Foreman OpenTofu Plugin
- 4 Architecture & Extensibility
- 5 'Live' Demo
- 6 Lessons learned & Roadmap

- ▶ Foreman supports many platforms through dedicated plugins:
 - ▶ vSphere
 - ▶ Proxmox
 - ▶ AWS
 - ▶ [oVirt]
 - ▶ etc.

The Real Problem

- ▶ Integrating new Platforms is hard
- ▶ Every new Platform requires its own Foreman Plugin & Fog Plugin
- ▶ Each plugin duplicates logic for provisioning and lifecycle
- ▶ Maintenance Overhead grows with platform count

Agenda

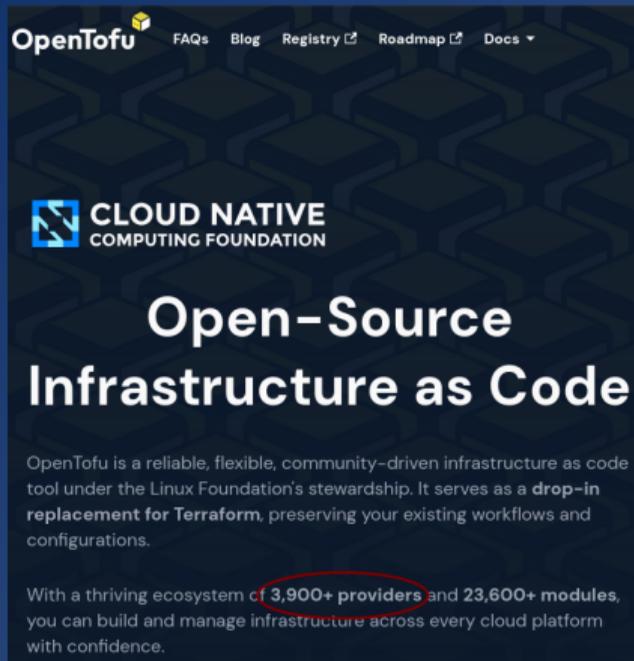

- 1 Foreman's current compute model
- 2 'Issues' with the current model
- 3 Introducing the Foreman OpenTofu Plugin
- 4 Architecture & Extensibility
- 5 'Live' Demo
- 6 Lessons learned & Roadmap

What 'Another Plugin' Costs

- ▶ Foreman knowledge required
- ▶ Testing and maintenance
- ▶ Verify against real-life environment
- ▶ Small platforms rarely justify the effort

Meanwhile...

- ▶ Heterogeneous Infrastructure
- ▶ ‘Digital Sovereignty’ push Platforms
- ▶ many Providers exist
- ▶ OpenTofu already handles diverse Platforms declaratively

The image shows a screenshot of the OpenTofu website. At the top left is the OpenTofu logo. To its right are navigation links: FAQs, Blog, Registry (with an external link icon), Roadmap (with an external link icon), and Docs (with a dropdown arrow). Below the navigation is the Cloud Native Computing Foundation logo. The main heading reads 'Open-Source Infrastructure as Code'. Below this is a paragraph: 'OpenTofu is a reliable, flexible, community-driven infrastructure as code tool under the Linux Foundation's stewardship. It serves as a **drop-in replacement for Terraform**, preserving your existing workflows and configurations.' At the bottom, another paragraph states: 'With a thriving ecosystem of **3,900+ providers** and 23,600+ modules, you can build and manage infrastructure across every cloud platform with confidence.' The text '3,900+ providers' is circled in red in the original image.

Agenda

- 1 Foreman's current compute model
- 2 'Issues' with the current model
- 3 Introducing the Foreman OpenTofu Plugin
- 4 Architecture & Extensibility
- 5 'Live' Demo
- 6 Lessons learned & Roadmap

Design Goal

- ▶ Keep Foreman as the control plane
- ▶ Delegate provisioning to a generic backend
- ▶ Unified lifecycle
- ▶ Provider-agnostic
- ▶ Declarative
- ▶ Extensible without 'Coding'

Why OpenTofu

- ▶ Declarative provisioning model
- ▶ Mature ecosystem of providers
- ▶ Well-understood lifecycle (plan/apply/destroy)
- ▶ Open and extensible

Design Parameters

- ▶ Single plugin for multiple providers
- ▶ Use OpenTofu to provision hosts
- ▶ Foreman remains authority for
 - ▶ UI
 - ▶ API
 - ▶ Lifecycle

What This Plugin Is (and Is Not)

It is:

- ▶ Generic compute provisioning layer
- ▶ Extensible via configuration

It is **not**:

- ▶ Replacement for existing plugins

Traditional vs OpenTofu Model

Traditional:

- ▶ One plugin per platform
- ▶ Duplicated Logic
- ▶ High (Dev-)Cost

OpenTofu:

- ▶ One Plugin
- ▶ Multiple Providers
- ▶ Logic written once

Agenda

- 1 Foreman's current compute model
- 2 'Issues' with the current model
- 3 Introducing the Foreman OpenTofu Plugin
- 4 Architecture & Extensibility
- 5 'Live' Demo
- 6 Lessons learned & Roadmap

High-Level Architecture

- ▶ Foreman Core:
 - ▶ UI/API/lifecycle
- ▶ OpenTofu Plugin:
 - ▶ Host → OpenTofu map
 - ▶ Provisioning abstraction
- ▶ OpenTofu Engine:
 - ▶ Plan/Apply/State
- ▶ Providers:
 - ▶ Nutanix, Hetzner, others

Provisioning Flow

1. Host defined in Foreman
2. Plugin maps host → OpenTofu resource
3. OpenTofu plan & apply executed
4. Provider creates resource
5. Foreman tracks host

State & Lifecycle Ownership

- ▶ OpenTofu manages infrastructure state
- ▶ Foreman manages host lifecycle
- ▶ Clear separation avoids duplicate state machines

Extensibility Model

- ▶ New compute platform = new OpenTofu provider
- ▶ No Foreman code changes required
- ▶ Resource types defined via configuration

Agenda

- 1 Foreman's current compute model
- 2 'Issues' with the current model
- 3 Introducing the Foreman OpenTofu Plugin
- 4 Architecture & Extensibility
- 5 'Live' Demo**
- 6 Lessons learned & Roadmap

- ▶ Configure OpenTofu provider (via Compute Resource)
- ▶ Define host provisioning via Foreman
- ▶ OpenTofu Script
- ▶ Configuration extension

Demo time

What This Enables

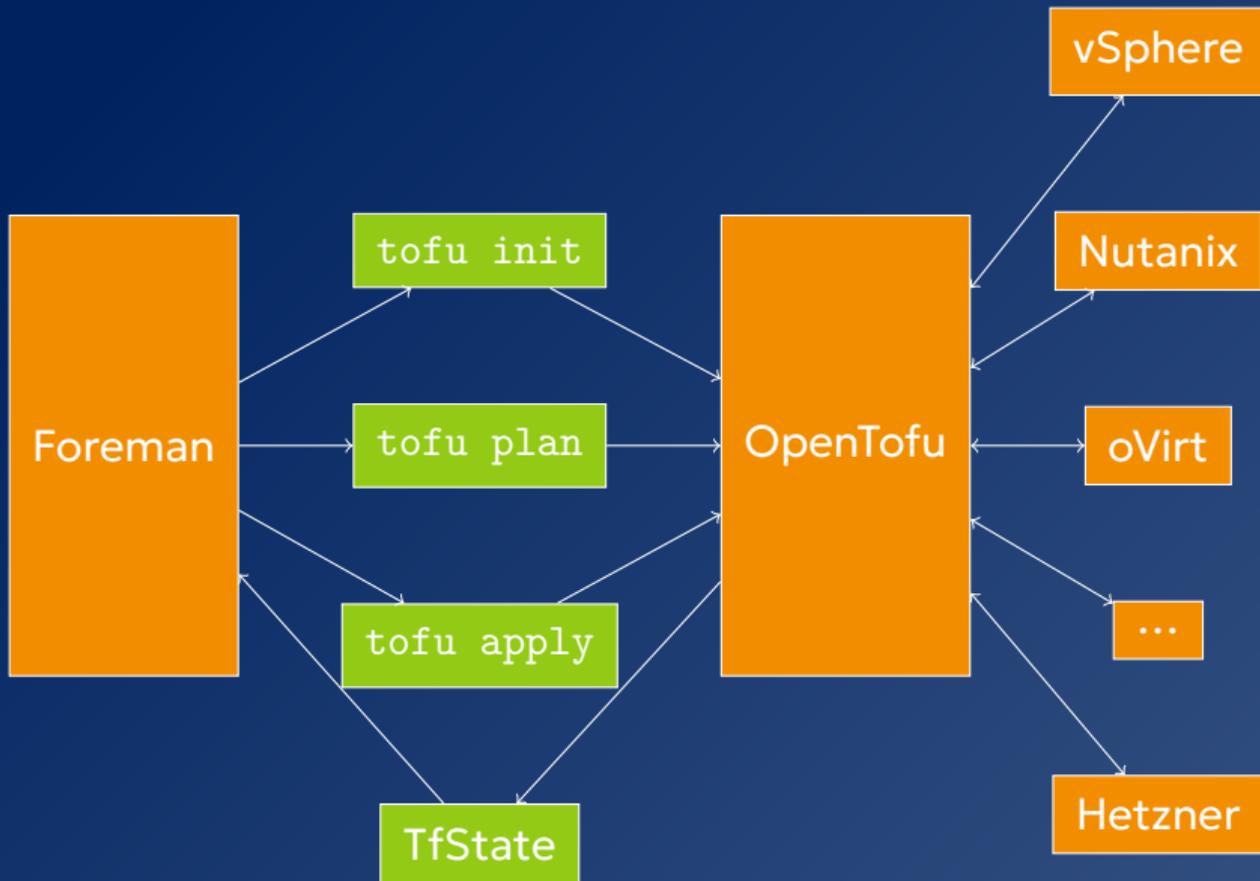

- ▶ One Foreman plugin to maintain
- ▶ Same provisioning workflow across platforms
- ▶ Faster onboarding of new compute providers
- ▶ Foreman scales with infrastructure diversity

Agenda

- 1 Foreman's current compute model
- 2 'Issues' with the current model
- 3 Introducing the Foreman OpenTofu Plugin
- 4 Architecture & Extensibility
- 5 'Live' Demo
- 6 Lessons learned & Roadmap

- ▶ Mapping declarative resources to hosts
- ▶ UX boundaries Foreman/OpenTofu
- ▶ Error handling & visibility
- ▶ TfState storage & storing information

Workflow visualized

- ▶ Less Configuration Options in UI?
- ▶ OpenTofu Knowledge required?
- ▶ Redundant state → divergence possible
- ▶ Not all Providers map cleanly to Foreman Hosts
- ▶ OpenTofu (Provider-)Limitations
 - ▶ Power State
 - ▶ Parameter changes might result in Host reset do not offer Parameter or show Warning

- ▶ More Provider-Types (e.g. Hetzner)
- ▶ Better state visibility (ideally integrated in Host-Details/-Edit)
- ▶ Simplify adding new Provider (1 file per Provider)
- ▶ Feature parity with traditional Compute Resource Plugins
 - ▶ Image based Deployment (if applicable)
 - ▶ Snapshots
- ▶ React UI

Key Takeaways

- ▶ Plugin-per-Platform doesn't scale
- ▶ OpenTofu is a generic backend
- ▶ Foreman remains Orchestration Control Plane
- ▶ 'Digital Sovereignty' might push certain Provider Types
- ▶ →
 - ▶ OpenTofu builds it
 - ▶ Ansible configures it
 - ▶ Foreman orchestrates it

Thanks

- ▶ Questions!?
- ▶ Contributions Welcome
